ABSTRACT - The present investigation proposes an efficient low power encoding scheme intended for a 5GS/s 5 bit flash analog to digital converter. The designing of a thermometer code to binary code is one of the challenging issues in the design of a high speed low power flash ADC. An encoder circuit in this paper translates the thermometer code into the intermediate gray code to reduce the effects of bubble errors. To maintain the high speed with low power dissipation, the implementation of the encoder through pseudo NMOS logic is presented. The proposed encoder is designed using 90nm technology in 1.2 V power supply using CADENCE tool. The simulation results shown for a sampling frequency of 5GHz and the average power dissipation of the encoder is 0.3149 mW which is very less in comparison with current mode logic encoder implementation.

Keywords – Analog to digital converter, Flash ADC, Pseudo NMOS logic, Pseudo Dynamic CMOS logic.

I. INTRODUCTION

The flash ADC is known for its fastest speed compared to other ADC architectures. Therefore, it is used for high-speed and very large bandwidth applications such as radar processing, digital oscilloscopes, high-density disk drives, and so on. The flash ADC is also known as the parallel ADC because of its parallel architecture.

Figure 1 illustrates a typical flash ADC block diagram. As shown in Fig. 1, this architecture needs $2^n - 1$ comparators for a n-bit ADC; for example, a set of 31 comparators is used for 5-bit flash ADC. Each comparator has a reference voltage that is provided by an external reference source. These reference voltages are equally spaced by $V_{LSB}$ from the largest reference voltage to the smallest reference voltage $V_{1}$. An analog input is connected to all comparators so that each comparator output is produced in one cycle. The digital output of the set of comparators is called the thermometer code and is being converted to gray code initially (for minimizing the bubble errors) and further changed into a binary code through the encoder [1]. However, the flash ADC needs a large number of comparators as the resolution increases. For instance, a 6-bit flash ADC needs 63 comparators, but 1023 comparators are needed for a 10-bit flash ADC. This exponentially increasing number of comparators requires a large die size and a large amount of power consumption [3].

The proposed encoder is designed using pseudo NMOS logic style for achieving highest sampling frequency of 5GS/s and low power dissipation with respect to current mode logic. The design of the encoder with detailed description is presented in section II. The implementation of the encoder using pseudo NMOS logic style is presented in section III. Simulation results and conclusion are provided in the subsequent sections.

II. DESIGN OF THE PROPOSED ENCODER

Conversion of the thermometer code output to binary code is one of the bottlenecks in high speed flash ADC design [2]. The bubble error usually results from timing differences between clock and signal lines and it is a situation where a ‘1’ is found above zero in thermometer code. For very fast input signals, small timing difference can cause bubbles in the output code. Depending on the number of successive zeroes, the bubbles are characterized as of first, second and higher orders. To reduce the effect of bubbles in thermometer code, one of the widely used methods is to convert the thermometer code to gray code [5, 6]. The truth table corresponding to 5 bit gray code is presented in Table1. The relationship between thermometer code, gray code and binary code is given below.

![Fig. 1 Flash ADC Block Diagram](image-url)
**G4 = T_{16}**

**G3 = T_5 \overline{T_{24}}**

**G2 = T_4 \overline{T_{12}} + T_{20} \overline{T_{28}}**

**G1 = T_2 \overline{T_6} + T_{10} \overline{T_{14}} + T_{18} \overline{T_{22}} + T_{26} \overline{T_{30}}** \hspace{1cm} (A)

**G0 = T_1 \overline{T_3} + T_4 \overline{T_7} + T_9 \overline{T_{11}} + T_{13} \overline{T_{15}} + T_{17} \overline{T_{19}} + T_{21} \overline{T_{23}} + T_{25} \overline{T_{27}} + T_{29} \overline{T_{31}}**

**B4 = G4**

**B3 = G3 \text{ XOR } B4**

**B2 = G2 \text{ XOR } B3**

**B1 = G1 \text{ XOR } B2** \hspace{1cm} (B)

**B0 = G0 \text{ XOR } B1**

The equations for this encoder are derived from the truth table provided in Table 1.

**Fig. 2 Schematic of two input AND Gate Using Pseudo NMOS Logic**

The basic structure of two inputs and gate using pseudo NMOS logic style is shown in Fig. 2. The PMOS transistor in the pull up network is connected to ground that will make the pull up network to be pulled on all the time. The output will be evaluated conditionally depending upon the value of the inputs in the pull down network. The inverter on the output transforms the inverted gate to non inverted gate. Since the voltage swing on the output and the overall functionality of the gate depend on the ratio of the NMOS and PMOS sizes, the transistor sizing is crucial in the implementation design.

The disadvantage with pseudo NMOS logic is that it has static power consumption. (The power dissipation occurs when a direct current flows between VDD and ground. That is when both pull up and pull down networks are switched on). The nominal high output voltage of (V_{OH}) of pseudo NMOS logic is VDD (Assuming that the pull down network is switched off) and the nominal low output voltage (V_{OL}) is not zero. This will results in reduced noise margins. For the implementation of the positive logics (eg: AND, OR gate) a static CMOS inverter is added at the output side. This will improve the noise margin of the circuit.

In spite of static power dissipation, the pseudo NMOS logic consumes less CMOS logic style. The advantage of static CMOS logic style is that it is having the lowest power consumption with a lower speed. So for achieving a low power with high speed, other logic styles are preferred. Here the design is implemented using logic style called pseudo NMOS logic.[8]

The pseudo NMOS logic circuit consists of a PMOS transistor with gate connected to ground, a bunch of NMOS transistors for the implementation of the logic style in the pull down network and an inverter. For the implementation of a specific logic circuit with N inputs, pseudo NMOS logic requires N+1 transistors instead of 2N transistors in comparison with static CMOS logic. Pseudo NMOS logic is an attempt to reduce the number of transistors with extra power dissipation and reduced robustness.

### III. IMPLEMENTATION OF PROPOSED ENCODER

There are different logic styles to implement the encoder design. Generally the implementation will be done using static
amount of power because of the reduced number of transistors and the absence of other components (resistors) used for the implementation in comparison with current mode logic.

The schematic of the gray code encoder for each bit is designed using the proposed logic is shown in Fig. 3. With the help of XOR gate, the gray code will be converted to binary code. The schematic of the two input XOR gate is shown in Fig. 4. The XOR gate is implemented with a pseudo dynamic CMOS logic [7] to maintain the synchronization with the clock. Pseudo dynamic CMOS logic circuit consists of a PMOS transistor with gate connected to clock, a bunch of NMOS transistors for the implementation of the logic style in the pull down network and an inverter. The transistor sizes are given in Table 2.

IV. SIMULATION RESULTS AND DISCUSSION

The encoder is designed as shown in Fig. 5 and tested using all the input combinations from the truth table and verified. At the output of the gray code a D flip-flop [Fig. 6] is added to get the undistorted waveform. The gray code output is shown in the Fig. 7. As derived from the equation (B), the gray code will be converted to binary code and the simulation results are shown in Fig. 8. The summary of the encoder simulation results is shown in the table. In most of the 5 bit flash
ADC’s, the maximum sampling frequency achieved can be up to 3.5GS/s [4]. With the use of proposed encoder maximum sampling frequency of 5GS/s can be achieved. The average power dissipation of the proposed encoder is 0.3149 mW. The results are presented and compared with current mode logic encoder [2] in the Table 3.

Table 3. Summary of Proposed Encoder

The results show that the new design consumes less power than the current mode logic encoder[2]. The power dissipation is reduced because of the usage of the reduced number of transistors for the implementation of the logic. In comparison with the static CMOS logic encoder, the proposed encoder contains a reduced number of transistors, thereby reducing the cost of the encoder also.

V. CONCLUSION

The speed and power of an encoder play an important role in the design of flash ADC. The proposed encoder uses a pseudo NMOS logic to reduce the power of the encoder. The encoder is designed and simulated using 90 nm technology using CADENCE tool. The encoder which is operating at 5 GHz, consumes 0.3149 mW from 1.2 V supply. The performance of the encoder makes it suitable for the design of high speed low power flash ADC.
